Bison

Bottom-Up Syntax Analysis

- Input: A stream of symbols (tokens)
- Output: A syntax tree or error
- Method: until input consumed or error do
 - shift next symbol or reduce by some production
 - decide what to do by looking k symbols ahead
- Properties
- Constructs the syntax tree in a bottom-up manner
- Finds the rightmost derivation (in reversed order)
- Reports error as soon as the already read part of the input is not a prefix of a program (valid prefix property)

Parsing *aabb* in the grammar G_{ab} with $S \rightarrow aSb|\epsilon$

Stack	Input	Action	Dead ends
\$	aabb#	shift	reduce $S \rightarrow \epsilon$
\$a	abb#	shift	reduce $S \rightarrow \epsilon$
\$aa	bb#	reduce $S \rightarrow \epsilon$	shift
\$aaS	bb#	shift	reduce $S \rightarrow \epsilon$
\$aaSb	<i>b</i> #	reduce $S \rightarrow aSb$	shift, reduce $S \rightarrow \epsilon$
\$aS	<i>b</i> #	shift	reduce $S \rightarrow \epsilon$
\$aSb	#	reduce $S \rightarrow aSb$	reduce $S \rightarrow \epsilon$
\$ <i>S</i>	#	accept	reduce $S \rightarrow \epsilon$

▲□▶ ▲課▶ ▲理▶ ★理▶ = 目 - の��

Issues:

- Shift vs. Reduce
- Reduce $A \rightarrow \beta$, Reduce $B \rightarrow \alpha \beta$

Parsing *aa* in the grammar $S \rightarrow AB, S \rightarrow A, A \rightarrow a, B \rightarrow a$

Stack	Input	Action	Dead ends
\$	aa#	shift	
\$a	a#	reduce $A \rightarrow a$	reduce $B \rightarrow a$, shift
\$A	a#	shift	reduce $S \rightarrow A$
\$Aa	#	reduce $B \rightarrow a$	reduce $A \rightarrow a$
\$AB	#	reduce $S \rightarrow AB$	
\$ <i>S</i>	#	accept	

◆□▶ ◆□▶ ★□▶ ★□▶ □ のQ@

Issues:

- Shift vs. Reduce
- Reduce $A \rightarrow \beta$, Reduce $B \rightarrow \alpha \beta$

Shift-Reduce Parsers

- The bottom-up Parser is a shift-reduce parser, each step is a shift: consuming the next input symbol or a reduction: reducing a suffix of the stack contents by some production.
- the problem is to decide when to stop shifting and make a reduction instead.

・ロト ・母 ト ・ ヨ ト ・ ヨ ・ うへの

a next right side to reduce is called a "handle", reducing too early: dead end, reducing too late: burying the handle.

LR-Parsers – Deterministic Shift–Reduce Parsers

Parser decides whether to shift or to reduce based on

- the contents of the stack and
- ► *k* symbols lookahead into the rest of the input

Property of the LR–Parser: it suffices to consider the topmost state on the stack instead of the whole stack contents.

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQ@

From P_G to LR–Parsers for G

- ► *P_G* has non-deterministic choice of expansions,
- LL-parsers eliminate non-determinism by looking ahead at expansions,
- LR-parsers pursue all possibilities in parallel (corresponds to the subset-construction in NFSM → DFSM).

Derivation

1. Characteristic finte-state machine of G, a description of P_G

◆□▶ ◆□▶ ★□▶ ★□▶ □ のQ@

- 2. Make deterministic
- 3. Interpret as control of a push down automaton
- 4. Check for "inedaquate" states

From P_G to LR–Parsers for G

- ▶ *P_G* has non-deterministic choice of expansions,
- LL-parsers eliminate non-determinism by looking ahead at expansions,
- LR-parsers pursue all possibilities in parallel (corresponds to the subset-construction in NFSM → DFSM).

Derivation

- 1. Characteristic finte-state machine of G, a description of P_G
- 2. Make deterministic
- 3. Interpret as control of a push down automaton
- 4. Check for "inedaquate" states

Characteristic Finite-State Machine of G

NFSM $ch(G) = (Q_c, V_c, \Delta_c, q_c, F_c)$ — the characteristic finte-state machine of G:

- $Q_c = It_G$ states: the items of G
- V_c = V_T ∪ V_N input alphabet: the sets of terminal and non-terminal symbols

•
$$q_c = [S' \rightarrow .S]$$
 — start state

► $F_c = \{ [X \to \alpha.] \mid X \to \alpha \in P \}$ — final states: the complete items

►
$$\Delta_c =$$

 $\{([X \to \alpha. Y\beta], Y, [X \to \alpha Y.\beta]) | X \to \alpha Y\beta \in P \text{ and}$
 $Y \in V_N \cup V_T \} \cup$
 $\{([X \to \alpha. Y\beta], \varepsilon, [Y \to .\gamma]) | X \to \alpha Y\beta \in P \text{ and} Y \to \gamma \in P \}$

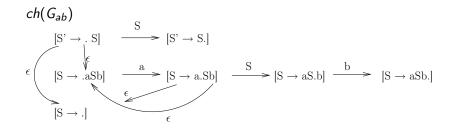

Item PDA for G_{ab} : $S \rightarrow aSb|\epsilon$

 $P_{G_{ab}}$

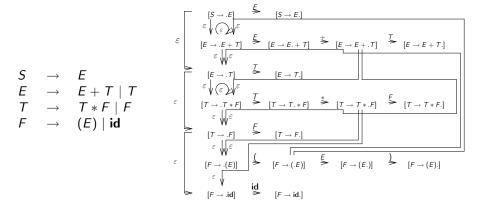

Stack	Input	New Stack
$[S' \rightarrow .S]$	ϵ	$[S' \rightarrow .S][S \rightarrow .aSb]$
$[S' \rightarrow .S]$	ϵ	$[S' \rightarrow .S][S \rightarrow .]$
$[S \rightarrow .aSb]$	а	[S ightarrow a.Sb]
$[S \rightarrow a.Sb]$	ϵ	$[S \rightarrow a.Sb][S \rightarrow .aSb]$
$[S \rightarrow a.Sb]$	ϵ	$[S \rightarrow a.Sb][S \rightarrow .]$
$[S \rightarrow aS.b]$	Ь	$[S \rightarrow aSb.]$
$[S \rightarrow a.Sb][S \rightarrow .]$	ϵ	$[S \rightarrow aS.b]$
$[S \rightarrow a.Sb][S \rightarrow aSb.]$	ϵ	[S ightarrow aS.b]
$[S' \rightarrow .S][S \rightarrow aSb.]$	ϵ	$[S' \rightarrow S.]$

Interpreting ch(G)

State of ch(G) is the *current* state of P_G , i.e. the state on top of P_G 's stack. Adding actions to the transitions and states of ch(G) to describe P_G :

 ε -transitions: push new state of ch(G) onto stack of P_G : new current state.

reading transitions: shifting transitions of P_G : replace current state of P_G by the shifted one.

final state: Actions in P_G :

- ▶ pop final state $[X \rightarrow \alpha]$ from the stack,
- do a transition from the new topmost state under X,
- push the new state onto the stack.

The Handle Revisited

 The bottom up-Parser is a shift-reduce-parser, each step is

 a shift: consuming the next input symbol, making a transition under it from the current state, pushing the new state onto the stack.

 a reduction: reducing a suffix of the stack contents by some production, making a transition under the left side non-terminal from the new current state, pushing the new state.

the problem is the localization of the "handle", the next right side to reduce.

reducing too early: dead end, reducing too late: burying the handle.

Handles and Reliable Prefixes

Some Abbreviations: RMD – rightmost derivation RSF – right sentential form $S' \stackrel{*}{\Longrightarrow} \beta Xu \stackrel{}{\longrightarrow} \beta \alpha u$ – a RMD of cfg *G*.

α is a handle of βαu.
 The part of a RSF next to be reduced.

Each prefix of βα is a reliable prefix. A prefix of a RSF stretching at most up to the end of the handle,

ション ふゆ くち くち くち くち

i.e. reductions if possible then only at the end.

Examples in G_0

RSF (<u>handle</u>)		Reason
		$S \Longrightarrow_{rm} E \Longrightarrow_{rm} E + T \Longrightarrow_{rm} E + F$
T * <u>id</u>		$S \stackrel{3}{\Longrightarrow} T * F \underset{rm}{\Longrightarrow} T * \mathbf{id}$
<u>F</u> * id		$S \stackrel{4}{\Longrightarrow} T * id \stackrel{\longrightarrow}{\Longrightarrow} F * id$
$T * \underline{id} + id$	T, T*, T*id	$S \stackrel{3}{\Longrightarrow} T * F \stackrel{\longrightarrow}{\longrightarrow} T * \mathbf{id}$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

Valid Items

 $[X \rightarrow \alpha.\beta]$ is **valid** for the reliable prefix $\gamma\alpha$, if there exists a RMD $S' \stackrel{*}{\Longrightarrow} \gamma X w \stackrel{\longrightarrow}{\longrightarrow} \gamma \alpha \beta w$. An item valid for a reliable prefix gives one interpretation of the parsing situation.

Some reliable prefixes of G_0

Viable Prefix	Valid Items	Reason	γ	w	X	α	β
E+	$[E \rightarrow E + .T]$	$S \underset{rm}{\Longrightarrow} E \underset{rm}{\Longrightarrow} E + T$	ε	ε	Ε	E+	Т
	$[T \rightarrow .F]$	$S \xrightarrow{*}_{rm} E + T _{rm} E + F$	E+	ε	Т	ε	F
	$[F \rightarrow .id]$	$S \xrightarrow{*}_{rm} E + F _{rm} E + \mathrm{id}$	E+	ε	F	ε	id
(E + ([F ightarrow (.E)]	$S \xrightarrow{*}_{rm} (E + F)$	(E+)	F	(E)
		$\xrightarrow[rm]{rm} (E + (E))$					

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 三臣 - 釣�?

Valid Items and Parsing Situations

Given some input string *xuvw*. The RMD $S' \stackrel{*}{\underset{rm}{\Longrightarrow}} \gamma X w \stackrel{}{\underset{rm}{\longrightarrow}} \gamma \alpha \beta w \stackrel{*}{\underset{rm}{\Rightarrow}} \gamma \alpha v w \stackrel{*}{\underset{rm}{\Rightarrow}} \gamma u v w \stackrel{*}{\underset{rm}{\Rightarrow}} x u v w$ describes the following sequence of partial derivations: $\gamma \stackrel{*}{\underset{rm}{\Rightarrow}} x \qquad \alpha \stackrel{*}{\underset{rm}{\Rightarrow}} u \qquad \beta \stackrel{*}{\underset{rm}{\Rightarrow}} v \qquad X \stackrel{}{\underset{rm}{\Rightarrow}} \alpha \beta$ $S' \stackrel{*}{\underset{rm}{\Rightarrow}} \gamma X w$ executed by the bottom-up parser in this order.

The valid item $[X \rightarrow \alpha . \beta]$ for the reliable prefix $\gamma \alpha$ describes the situation after partial derivation 2, that is, for RSF $\gamma \alpha v w$

Theorems

$$ch(G) = (Q_c, V_c, \Delta_c, q_c, F_c)$$

Theorem

For each reliable prefix there is at least one valid item.

Every parsing situation is described by at least one valid item.

Theorem

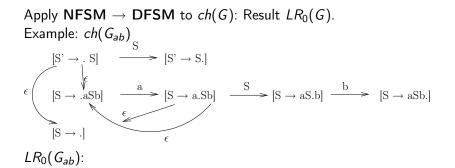

Let $\gamma \in (V_T \cup V_N)^*$ and $q \in Q_c$. $(q_c, \gamma) \vdash_{ch(G)}^* (q, \varepsilon)$ iff γ is a reliable prefix and q is a valid item for γ .

A reliable prefix brings ch(G) from its initial state to all its valid items.

Theorem

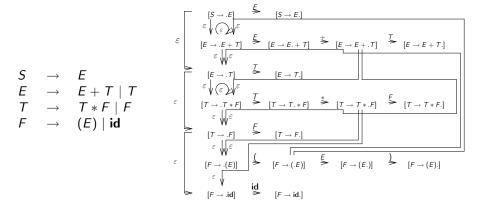

The language of reliable prefixes of a cfg is regular.

Making ch(G) deterministic

 $LR_0(G_0)$

The States of LR_0 $S_0 = \{ [S \rightarrow .E], F \}$	S ₅		s of Items $[F \rightarrow id.]$
	S ₆ ∗ F],		$ \begin{array}{l} [E \rightarrow E + .T], \\ [T \rightarrow .T * F], \\ [T \rightarrow .F], \\ [F \rightarrow .(E)], \\ [F \rightarrow .id] \end{array} $
$S_1 = \{ \begin{array}{c} [S \to E.], \\ [E \to E] \end{array} $	S ₇ ⊢ 7]}		
$S_2 = \{ egin{array}{c} [E ightarrow T.], \ [T ightarrow T.], \end{array}$		= {	
$S_3 = \{ [T \rightarrow F.] \}$	} <i>S</i> 9		$[E \rightarrow E + T.], \\ [T \rightarrow T. * F] \}$
$S_4 = \{ [F \to (.E)] \\ [E \to .E] $		= {	$[T \rightarrow T * F.]\}$
$\begin{bmatrix} E \rightarrow . T \end{bmatrix}$ $\begin{bmatrix} T \rightarrow . T \end{bmatrix}$ $\begin{bmatrix} T \rightarrow . F \end{bmatrix}$ $\begin{bmatrix} F \rightarrow . (E) \end{bmatrix}$	S ₁₁ * F]	= {	$[F \rightarrow (E).]$
[F ightarrow .id]	}		《日》《圖》《臣》《臣》 唐 めんの

Theorems

$$ch(G) = (Q_c, V_c, \Delta_c, q_c, F_c) \text{ and } LR_0(G) = (Q_d, V_N \cup V_T, \Delta, q_d, F_d)$$

Theorem

Let γ be a reliable prefix and $p(\gamma) \in Q_d$ be the uniquely determined state, into which $LR_0(G)$ transfers out of the initial state by reading γ , i.e., $(q_d, \gamma) \models_{LR0(G)}^* (p(\gamma), \varepsilon)$. Then

(a) $p(\varepsilon) = q_d$ (b) $p(\gamma) = \{q \in Q_c \mid (q_c, \gamma) \vdash^*_{ch(G)} (q, \varepsilon)\}$

(c) $p(\gamma) = \{i \in It_G \mid i \text{ valid for } \gamma\}$

- (d) Let Γ the (in general infinite) set of all reliable prefixes of G. The mapping $p: \Gamma \to Q_d$ defines a finite partition on Γ .
- (e) $L(LR_0(G))$ is the set of reliable prefixes of G that end in a handle.

 G_0

 $\gamma = \mathbf{E} + \mathbf{F}$ is a reliable prefix of G_0 . With the state $p(\gamma) = S_3$ are also associated: F, (F, ((F, ((F, ..., F, .., F, ..., F, ...,T * (F, T * ((F, T * (((F, ..., F)))))))E + F, E + (F, E + ((F, ..., E + (F, E + ((F, ..., E + (F, E +Regard S_6 in $LR_0(G_0)$. It consists of all valid items for the reliable prefix E+, i.e., the items $[E \rightarrow E + .T], [T \rightarrow .T * F], [T \rightarrow .F], [F \rightarrow .id], [F \rightarrow .(E)].$ Reason: E+ is prefix of the RSF E+T; $S \Longrightarrow_{rm} E \Longrightarrow_{rm} E + T \Longrightarrow_{rm} E + F \Longrightarrow_{rm} E + id$ \uparrow \uparrow \uparrow are valid. Therefore $[E \rightarrow E + .T]$ $[T \rightarrow .F]$ $[F \rightarrow .id]$ ション ふゆ くち くち くち くち

What the $LR_0(G)$ describes

 $LR_{0}(G) \text{ interpreted as a PDA } P_{0}(G) = (\Gamma, V_{T}, \Delta, q_{0}, \{q_{f}\})$ $\Gamma, \text{ (stack alphabet): the set } Q_{d} \text{ of states of } LR_{0}(G).$ $q_{0} = q_{d} \text{ (initial state): in the stack of } P_{0}(G) \text{ initially.}$ $q_{f} = \{[S' \rightarrow S.]\} \text{ the final state of } LR_{0}(G),$ $\Delta \subseteq \Gamma^{*} \times (V_{T} \cup \{\varepsilon\}) \times \Gamma^{*} \text{ (transition relation):}$ Defined as follows:

・ロト ・ 日 ・ ・ ヨ ・ ・ 日 ・ うらつ

$LR_0(G)$'s Transition Relation

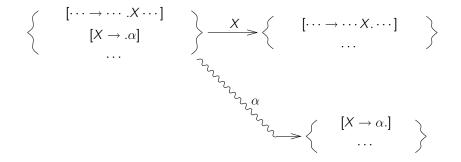

shift: $(q, a, q \, \delta_d(q, a)) \in \Delta$, if $\delta_d(q, a)$ defined. Read next input symbol a and push successor state of q under a (item $[X \to \cdots .a \cdots] \in q$). reduce: $(q \, q_1 \dots q_n, \varepsilon, q \, \delta_d(q, X)) \in \Delta$, if $[X \to \alpha.] \in q_n, \ |\alpha| = n$. Remove $|\alpha|$ entries from the stack. Push the successor of the new topmost state under Xonto the stack.

Note the difference in the stacking behavior:

- ► the Item PDA P_G keeps on the stack only one item for each production under analysis,
- ▶ the PDA described by the $LR_0(G)$ keeps $|\alpha|$ states on the stack for a production $X \to \alpha\beta$ represented with item $[X \to \alpha.\beta]$

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQ@

Reduction in PDA $P_0(G)$

Some observations and recollections

- also works for reductions of ϵ ,
- each state has a unique entry symbol,
- the stack contents uniquely determine a reliable prefix,
- current state (topmost) is the state associated with this reliable prefix,
- current state consists of all items valid for this reliable prefix.

・ロト ・ 日 ・ ・ ヨ ・ ・ 日 ・ うらつ

Non-determinism in $P_0(G)$

 $P_0(G)$ is non-deterministic if either Shift-reduce conflict: There are shift as well as reduce transitions out of one state, or Reduce-reduce conflict: There are more than one reduce

Reduce–reduce conflict: I here are more than one reduce transitions from one state.

States with a shift-reduce conflict have at least one read item $[X \rightarrow \alpha . a \beta]$ and at least one complete item $[Y \rightarrow \gamma.]$.

States with a reduce–reduce conflict have at least two complete items $[Y \rightarrow \alpha.], [Z \rightarrow \beta.].$

A state with a conflict is **inadequate**.

 $LR_0(G_0)$ has three inadequate states, S_1 , S_2 and S_9 .

- S_1 : Can reduce E to S (complete item $[S \rightarrow E.]$) or read "+" (shift-item $[E \rightarrow E. + T]$);
- S_2 : Can reduce T to E (complete item $[E \rightarrow T.]$) or read "*" (shift-item $[T \rightarrow T. * F]$);
- S₉: Can reduce E + T to E (complete item $[E \rightarrow E + T.]$) or read "*" (shift-item $[T \rightarrow T. * F]$).

$\blacktriangleright L(G_2) = L(G_1)$

- G_2 is LR(1)–grammar.
- ► Critical RSF *abⁿw*.
 - 1 : w = b implies, handle in w;
 - 1 : w = c implies, last b in b^n is handle.

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQ@

- $\begin{array}{l} \mathsf{Cfg} \ \mathsf{G}_2 \ \mathsf{with} \\ \mathsf{S} \ \to \ \mathsf{aAc} \end{array}$
- $A \rightarrow bbA \mid b.$
 - $\blacktriangleright L(G_2) = L(G_1)$
 - G_2 is LR(1)–grammar.
 - Critical RSF abⁿw.
 - 1 : w = b implies, handle in w;
 - 1: w = c implies, last b in b^n is handle.

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQ@

Cfg G_3 with $S \rightarrow aAc$ $A \rightarrow bAb \mid b$. ► $L(G_3) = L(G_1)$, • G_3 is not LR(k)-grammar for arbitrary k.

Cfg G_3 with $S \rightarrow aAc$ $A \rightarrow bAb \mid b$. ► $L(G_3) = L(G_1)$, ► G₃ is not LR(k)-grammar for arbitrary k. Choose an arbitrary k. Regard two RMDs $S \stackrel{*}{\Longrightarrow} ab^n Ab^n c \stackrel{}{\Longrightarrow} ab^n bb^n c$ $S \stackrel{*}{\underset{rm}{\Longrightarrow}} ab^{n+1}Ab^{n+1}c \stackrel{*}{\underset{rm}{\Longrightarrow}} ab^{n+1}bb^{n+1}c$ where $n \ge k$ Choose $\alpha = ab^n$, $\beta = b$, $\gamma = ab^{n+1}$, $w = b^n c$, $v = b^{n+2} c$. It holds $k : w = k : v = b^k$. $\alpha \neq \gamma$ implies that G_3 is not an LR(k)-grammar.

Adding Lookahead

Lookahead will be used to resolve conflicts.

The context-free items can be regarded as LR(0)-items if $[X \rightarrow \alpha_1.\alpha_2, \{\varepsilon\}]$ is identified with $[X \rightarrow \alpha_1.\alpha_2]$.

Example from G_0

(1)
$$[E \rightarrow E + .T, \{\}, +, \#\}]$$
 is a valid LR(1)-item for $(E+$
(2) $[E \rightarrow T., \{*\}]$ is not a valid LR(1)-item for
any reliable prefix
Reason:

cason.

(1)
$$S' \stackrel{*}{\Longrightarrow}_{rm} (E) \stackrel{*}{\Longrightarrow}_{rm} (E+T) \stackrel{*}{\Longrightarrow}_{rm} (E+T+id)$$
 where

$$\alpha = (, \ \alpha_1 = E+, \ \alpha_2 = T, \ u = +, \ w = +id)$$

▲□▶ ▲課▶ ▲理▶ ★理▶ = 目 - の��

(2) The string E* can occur in no RMD.

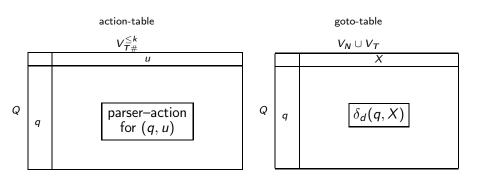

LR–Parser

Take their decisions (to shift or to reduce) by consulting

- the reliable prefix γ in the stack, actually the by γ uniquely determined state (on top of the stack),
- the next k symbols of the remaining input.
- Recorded in an action-table.
- ► The entries in this table are: *shift:* read next input symbol; *reduce* $(X \rightarrow \alpha)$: reduce by production $X \rightarrow \alpha$; *error:* report error *accept:* report successful termination.

A goto-table records the transition function of the $LR_0(G)$.

The action- and the goto-table

```
Construction of LR(1)-Parsers
```

```
Classes of LR-Parsers:

canonical LR(1): analyze languages of LR(1)-grammars,

SLR(1): use FOLLOW<sub>1</sub> to resolve conflicts,

size is size of LR(0)-parser,

LALR(1): refine lookahead sets compared to FOLLOW<sub>1</sub>,

size is size of LR(0)-parser.

BISON is an LALR(1)-parser generator.
```

LR(1)–Conflicts

Set of LR(1)-items *I* has a shift-reduce-conflict: if exists at least one item $[X \rightarrow \alpha.a\beta, L_1] \in I$ and at least one item $[Y \rightarrow \gamma., L_2] \in I$, and if $a \in L_2$. reduce-reduce-conflict:

> if it contains at least two items $[X \to \alpha_{.}, L_1]$ and $[Y \to \beta_{.}, L_2]$ where $L_1 \cap L_2 \neq \emptyset$.

> > ・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・ うらつ

A state with a conflict is called **inadequate**.

Construction of an LR(1)-Action Table

```
Input: set of LR(1)-states Q without inadequate states
Output: action-table
Method:
foreach q \in Q do
    foreach LR(1)-item [K, L] \in q do
        if K = [S' \rightarrow S.] and L = \{\#\}
        then action[q, \#] := accept
        elseif K = [X \rightarrow \alpha.]
        then foreach a \in I do
                action[q, a] := reduce(X \rightarrow \alpha)
                od
        elseif K = [X \rightarrow \alpha . a\beta]
        then action[q, a] := shift
        fi
    od
od:
```

```
for
each q \in Q and a \in V_T such that action[q, a] is undef. do
action[q, a] := error
od;
```

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQ@

    od
end
```

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・ うらつ

- The test "q' not in Q" uses an equality test on LR(1)-items. $[K_1, L_1] = [K_2, L_2]$ iff $K_1 = K_2$ and $L_1 = L_2$.
- ▶ The canonical LR(1)-parser generator splits LR(0)-states.
- LALR(1)-parsers could be generated by
 - using the equality' test $[K_1, L_1] = [K_2, L_2]$ iff $K_1 = K_2$.
 - and replacing an existing state q" by a state, in which equal' items [K₁, L₁] ∈ q' and [K₂, L₂] ∈ q" are merged to new items [K₁, L₁ ∪ L₂].

ション ふゆ くち くち くち くち

Example from G_0 $S_0' = Closure(Start)$ $S'_6 = Closure(Succ(S'_1, +))$ $= \{ [S \rightarrow .E, \{\#\}] \}$ $= \{ [E \rightarrow E + T, \overline{\{\#, +\}}] \}$ $[E \rightarrow .E + T, \{\#, +\}],$ $[T \to .T * F. \{\#, +, *\}].$ $[E \to .T, \{\#, +\}],$ $[T \to .F, \{\#, +, *\}].$ $[T \rightarrow .T * F, \{\#, +, *\}],$ $[F \rightarrow .(E), \{\#, +, *\}].$ $[T \to .F, \{\#, +, *\}],$ $[F \rightarrow .id, \{\#, +, *\}]$ $[F \rightarrow .(E), \{\#, +, *\}],$ $[F \rightarrow .id. \{\#, +, *\}]$ $S'_{o} = Closure(Succ(S'_{6}, T))$ $= \{ [E \rightarrow E + T_{..} \{ \#, + \}], \}$ $[T \rightarrow T, *F, \{\#, +, *\}]$ $S'_1 = Closure(Succ(S'_0, E))$ $= \{ [S \rightarrow E_{..}, \{\#\}], \}$ $[E \rightarrow E. + T, \{\#, +\}]$

$$\begin{array}{l} S_2' = & \textit{Closure}(\textit{Succ}(S_0', T)) \\ &= \{ [E \rightarrow T_{\cdot}, \{\#, +\}], \\ & [T \rightarrow T_{\cdot} * F, \{\#, +, *\}] \end{array} \} \\ \\ \text{Inadequate LR(0)-states } S_1, S_2 \text{ und } S_9 \text{ are adequate after adding lookahead sets.} \end{array}$$

 S'_1 shifts under "+", reduces under "#". S'_2 shifts under "*", reduces under "#" and "+", S'_9 shifts under "*", reduces under "#" and "+".

Non-canonical LR-Parsers

SLR(1)- and LALR(1)-Parsers are constructed by

- 1. building an LR(0)-parser,
- 2. testing for inadequate LR(0)-states,
- 3. extending complete items by lookahead sets,
- 4. testing for inadequate LR(1)-states.

The lookahead set for item $[X \to \alpha.\beta]$ in q is denoted $LA(q, [X \to \alpha.\beta])$ The function $LA : Q_d \times It_G \to 2^{V_T \cup \{\#\}}$ is differently defined for $SLR(1) \ (LA_S)$ und $LALR(1) \ (LA_L)$. SLR(1)- and LALR(1)-Parsers have the size of the LR(0)-parser, i.e., no states are split.

Constructing SLR(1)–Parsers

- ▶ Add $LA_S(q, [X \rightarrow \alpha]) = FOLLOW_1(X)$ to all complete items;
- Check for inadequate SLR(1)-states.
- ▶ Cfg G is SLR(1) if it has no inadequate SLR(1)-states.

Example from G_0 :

Extend the complete items in the inadequate states S_1 , S_2 and S_9 by *FOLLOW*₁ as their lookahead sets.

$S_1''=\{$	$[S \rightarrow E., \{\#\}],$	conflict removed,
	$[E \rightarrow E. + T]$	" + " is not in $\{\#\}$

 $\begin{array}{ll} S_2'' = \{ & [E \rightarrow T., \{\#, +,)\}], & \quad \mbox{conflict removed,} \\ & [T \rightarrow T. *F] \end{array} \} & \quad \ \ " *" \mbox{ is not in } \{\#, +,)\} \end{array}$

 $\begin{aligned} S_9'' &= \{ & [E \to E + T., \{\#, +, \}\}], \text{ conflict removed,} \\ & [T \to T. *F] \} & "*" \text{ is not in } \{\#, +, \} \\ G_0 \text{ is an SLR}(1) &= \text{grammar.} \end{aligned}$

A Non–SLR(1)–Grammar

Slightly abstracted form of the C-assignment.

▲□▶ ▲課▶ ▲理▶ ★理▶ = 目 - の��

States of the LR–DFSM as sets of items $S_0 = \{ [S' \rightarrow .S], S_5 = \{ [L \rightarrow id.] \}$ $S_1 = \{ [S' \rightarrow S_.] \} \quad S_7 = \{ [L \rightarrow *R_.] \}$ $S_2 = \{ [S \rightarrow L. = R], S_8 = \{ [R \rightarrow L.] \}$ $[R \rightarrow L.]$ } $S_9 = \{ [S \rightarrow L = R.] \}$ $S_3 = \{ [S \rightarrow R.] \}$ $S_4 = \{ [L \rightarrow *.R],$ $[R \rightarrow .L],$ $[L \rightarrow . * R],$ $[L \rightarrow .id]$

 S_2 is the only inadequate LR(0)-state.

Extend $[R \to L] \in S_2$ by $FOLLOW_1(R) = \{\#, =\}$ does not remove the shift reduce conflict gives the symplet to shift "-" is in the local head set

LALR(1)-Parsers SLR(1): $LA_{S}(q, [X \rightarrow \alpha]) =$ $\{a \in V_{T} \cup \{\#\} \mid S' \# \stackrel{*}{\Longrightarrow} \beta Xa\gamma\} = FOLLOW_{1}(X)$ LALR(1): $LA_{L}(q, [X \rightarrow \alpha]) =$ $\{a \in V_{T} \cup \{\#\} \mid S' \# \stackrel{*}{\Longrightarrow} \beta Xaw \text{ and } \delta^{*}_{d}(q_{d}, \beta\alpha) = q\}$ Lookahead set $LA_{L}(q, [X \rightarrow \alpha])$ depends on the state q.

- Add $LA_L(q, [X \rightarrow \alpha])$ to all complete items;
- Check for inadequate LALR(1)-states.
- ▶ Cfg G is LALR(1) if it has no inadequate LALR(1)-states.
- Definition is not constructive.
- Construction by modifying the LR(1)-Parser Generator, merging items with identical cores.

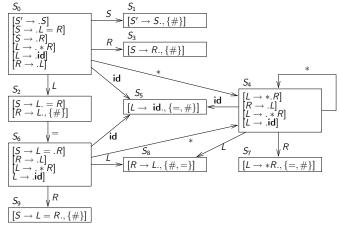

```
The Size of LR(1) Parsers
```

The number of states of canonical and non-canonical LR(1) parsers for Java and C:

▲□▶ ▲課▶ ▲理▶ ★理▶ = 目 - の��

	C	Java
LALR(1)	400	600
LR(1)	10000	12000

Non-SLR-Example

Grammar is LALR(1)–grammar.

Interesting Non LR(1) Grammars

► Common "derived" prefix $\begin{array}{rcl}
A & \to & B_1 ab \\
A & \to & B_2 ac \\
B_1 & \to & \epsilon \\
B_2 & \to & \epsilon
\end{array}$

Optional non-terminals
